Abstract

Artificial intelligence (AI) is transforming how Human Resource Management (HRM) practises and professional activities take place, which triggers employees' worries about losing the job, being surveilled, and being substituted by machines. This paper analyses the role of transformational leadership (TFL) in mitigating workers' anxiety while implementing AI technologies based on the secondary data analysis and systematic literature review (SLR). The study aims to assess whether and how TFL affects employees' uncertainty regarding technology and influences their readiness to adopt innovations. The research design was applied to the qualitative data gathered from the empirical articles published between 2021 and 2026. The findings revealed that transformational leadership lessens the adverse impact of algorithmic anxiety on self-esteem and intentions to use the new technology. The study conceptualised the relationships between the four components of transformational leadership, including idealized influence, inspirational motivation, intellectual stimulation, and individualised consideration, and workers' responses to implementing AI in line with the theoretical model of communication and uncertainty management (TCUM) and job demands – resources (JD-R). The study demonstrated that transformational leadership plays a pivotal role in reducing workers' anxiety while introducing new technologies. The analysis concluded that managing and mitigating algorithmic anxiety requires transformational leadership, which empowers workers and promotes their cognitive abilities. Based on the findings, this paper provides practical implications for leaders in charge of post-adoption processes and transformational leadership practices to ensure that employees are not just technologically competent but emotionally intelligent as well.

Keywords: Transformational Leadership, Algorithmic Anxiety, Artificial Intelligence in HRM, Employee AI Adoption, Psychological Safety, Future of Work, Secondary Data Analysis.

1. INTRODUCTION

The introduction of new technologies has changed many aspects of the functioning of organizations. One such component is Human Resource Management, which has transformed from a primarily recordkeeping function to a dynamic process with the use of predictive analytics, screening, performance evaluations, and other automated tools. More recently, organizations have demonstrated increased interest in using artificial intelligence (AI) in managing and improving their human capital. The application of AI technologies in human resource management practices has the potential to bring significant benefits to organizations by automatizing various labour-intensive processes. At the same time, there are several challenges associated with transforming and improving human resource management practices using AI.

Most of the literature on the use of AI in human resource management practices discusses this issue from the perspective of either employees or organizations. However, there is also a need to consider the psychological side of this process. Employees who have been managing and improving human capital in traditional ways for a substantial part of their careers may feel intimidated by the prospect of interacting with AI. Moreover, they may perceive this transformation as a threat to their professional superiority, which may lead to detrimental consequences for organizations, including performance decrement and disengagement. Researchers have identified the phenomenon of algorithmic anxiety, which encompasses various adverse psychological consequences stemming from the introduction of algorithmic decision-making technologies. Although algorithmic anxiety has been linked to negative individual- and organizational-level outcomes, little is known about how it can be alleviated.

Most of the scholarly works devoted to the use of AI in human resource management practices address this issue primarily from the perspective of employees' acceptance of this innovation. Communication with AI, as a new and often intimidating phenomenon, has been the subject of extensive research in the field of technology acceptance. Many scholars have devoted their efforts to identifying strategies that could facilitate employees' adaptability to new realities. However, the focus of this paper is on transformational leadership (TFL). This study will explore the mediating role of TFL in employees' ability to effectively adapt to changes and manage algorithmic anxiety.

Specifically, this paper will achieve three objectives. First, it will review and synthesize the extant literature on the relationship between algorithmic anxiety, transformational leadership, and technology acceptance. Second, it will identify the mechanisms through which TFL can mitigate the severity of algorithmic anxiety, thus facilitating employees' adaptation to changes. Finally, this paper will provide practical recommendations based on the findings and discuss their implications for further scholarly research. By doing so, this study will make a significant

contribution to the extant literature, as it will provide a different perspective on the issue of adapting to algorithmic decision-making technologies.

2. LITERATURE REVIEW

2.1 The Concept of Algorithmic Anxiety in HRM

Artificial Intelligence (AI) anxiety in the workplace is "a multi-faceted construct comprising of feelings of helplessness, powerlessness and fears of loss of autonomy in the face of artificial intelligence." In relation to the human resource management (HRM) context, algorithmic anxiety may be explained by three key mechanisms or phenomena. The first phenomenon is role transformation anxiety which is brought about by employees' fears that their work roles will be transformed through the introduction of automated sub-processes thus eliminating or devaluing their roles as professionals. The second phenomenon is the issue of accountability which arises when there is a wrong or undesirable algorithmic outcome and raises the question of who between humans and robots should be held accountable. The third phenomenon is the black box dilemma which reflects employees' anxieties and lack of trust in the decision-making processes of algorithmic systems.

As discussed in the literature, employees tend to embrace a "healthy" fear of robots in the workplace for eliminating their role in decision-making and other activities that were previously performed by humans. In other words, algorithmic anxiety is likely to impact employees' mental states and, consequently, the organization's productivity in a negative manner. First, the anxiety will lead to reduced psychological and, therefore, organizational energy thus lowering performance levels. Second, the fear of robots is also likely to cause employee demotivation, apathy, and burnout which are detrimental to achieving the goals of the business and HRM outcomes.

2.2 Transformational Leadership in the Digital Era

Transformational leadership is defined as a leadership model different from transactional and exchange-based leadership style, which is characterized by the focus on the leader's vision, engagement, and ability to motivate subordinates to follow through with the realization of their best capabilities as opposed to only potential capabilities. In short, while transactional leadership aims at securing compliance with the leader's desires, transformational leadership inspires the followers' identification with the leader and the leader's vision. As such, transformation leadership is much more effective in contexts where disruptive change is taking place and requires people to adjust significantly to the new circumstances, including new systems and tools, such as artificial intelligence. At the time of disruptive change, the mere enforcement of the necessity to implement new practices and tools will only intensify the negative feelings

associated with them, such as fear or anxiety; instead, transformational leadership tackles these negative feelings at the source by addressing the followers' concerns which are the major driver behind disruptive change.

There are four key aspects of transformational leadership which are pertinent in the context of disruptive change associated with the implementation of new tools, such as artificial intelligence, including idealized influence, inspirational motivation, intellectual stimulation, and individualized consideration, all of which help address the sources of concern specific to disruptive change scenarios.

Idealized influence stems from the leader's ability to serve as a role model for one's team. In the context of the disruptive change scenario, this implies addressing the followers' concerns by sharing one's apprehensions and concerns about the utilization of new systems and tools, including artificial intelligence. As such, instead of exercising power derived from the leader's positional authority to enforce the decision to implement new systems and tools, the transformational leader exercising idealized influence addresses the team's concerns by sharing and discussing one's own concerns.

Inspirational motivation is transformational leadership's ability to communicate the leader's vision effectively to inspire the team and increase the followers' perception of the likelihood of achieving the envisioned future state. In the context of disruptive change, this aspect of transformational leadership helps the leader tackle the followers' concerns by articulating the organization's or team's vision to secure the followers' support. When communicating the vision, the transformational leader should focus on creating the sense of opportunity, addressing the followers' fears, and enhancing their efficacy beliefs, thereby reducing the levels of danger they feel threatened by the disruption-provoking change.

Intellectual stimulation is the transformational leader's ability to encourage the team to engage in creative behaviours, "risky" experiments, and behaviours conducive to realizing the leader's vision. In the disruptive change context, this includes addressing the followers' concerns by engaging the team in co-creation of approaches to utilizing AI as new opportunities to achieve the envisioned positive change. However, as the followers' fears and concerns will often manifest themselves in aversion to experimentation, even if they appear rational and justified, it is the responsibility of the transformation leader to alleviate the followers' fears, which, in case of AI-related change, are largely related to embarrassment in front of the new technology. Intellectual stimulation is vital in fostering the followers' realization of their own potential to effectively utilize the new systems and tools.

Finally, individualized consideration refers to the leader's ability to listen to one's team and adjust the approach to leading them based on their individual requirements and needs. When addressing the concerns of the team in the context of disruptive change, individualized consideration is vital since individualized response is critical in helping the followers to effectively navigate individual concerns. In other words, one should not respond to individual concerns in the same way, since these are individual experiences stemming from the same source of threat. For instance, when addressing the concerns of an individual who struggled with technology utilization in the past or who does not see themselves as technology-savvy, the transformational leader should provide more individualized consideration to facilitate this individual's ability to overcome their fears and concerns.

2.3 TFL as a Psychological Buffer

Some of the recent studies have begun to conceptualize the role of transformational leadership (TFL) not only as a process, through which agents better their ability to manage change, but also as a capacity to create the certain level of psychological safety within a team or organization. Such a mechanism is especially effective in the context of managing "work and technological change" because it allows for engaging in "reflexive exploration" of new possibilities created by disruptive technologies, such as AI. In other words, psychological safety enables one to be open to the emerging opportunities with disruptive innovations at work, leading to their higher likelihood to be integrated and utilized in one's work routines.

Transformational leaders are likely to promote such a critical approach to change by framing the threats to one's job security, which change usually involves, as win-win scenarios for both employees and employers. In addition, it is important to note that, as the recent article by Lim & Kim (2026) suggests, TFL practices do not have a direct influence on one's intention to embrace generative AI in their work but rather affect it indirectly through enhancing AI literacy and self-efficacy beliefs regarding technology use, which then lead to higher rates of technology adoption. Thus, transformational leadership practices affect the psychological environment, within which one operates, thereby impacting their ability to acquire new competencies and utilize emerging opportunities, such as generative AI, at work.

2.4 Barriers to AI Adoption in Decision-Making

Although the effectiveness of TFL is not doubted, there are a few factors that might prevent the use of AI for making decisions in the workplace. Firstly, the social nature of humans works against the implementation of artificial intelligence, as people would attribute their successes and failures to a more competent level above them, rather than an unbiased algorithm. Secondly, the legal and regulatory environment might work against the adoption of such technology. In other

words, if a specific state requires organizations to justify their actions towards their employees or prohibit the use of such technology, the problem will have to be resolved before implementing the system. Thirdly, the black box dilemma described above constitutes another challenge for adopting AI in the workplace, as the inability of an executive to explain the inner workings of the system to the employee who asked would decrease the practicality of such software tremendously. Finally, the fourth factor that might prevent the use of AI for making decisions in the workplace is the ability of current decision-makers to delegate their responsibilities to an algorithm, thus diminishing their own authority over the process. It is possible to suggest that the given factor would lead to inevitable resistance to the proposed change, the extent of which is impossible to predict. Overall, it is possible to conclude that each of the factors listed above poses a significant threat to an organization's ability to use AI in making decisions in the workplace. With the ability to trust the system being the primary factor that differentiates the perspectives of employees described in the article, it is possible to assume that each obstacle stems from this characteristic and attempts to resolve it in some way.

2.5 Theoretical Framework: TCUM and the JD-R Model

The current research is guided by two theoretical models that can be applied to investigate the impact of uncertainty sources. The first is the Theory of Communication and Uncertainty Management (TCUM) that views uncertainty as a stimulus for which people can develop a response depending on how they evaluate this situation. TCUM applied to the proposed research helps explain how the use of artificial intelligence can contribute to employees' ambiguity. Then, the leader should manage communication and deal with uncertainty to minimize its impact on the employees.

The second theory is the Job Demands-Resources theory (JD-R) that explains algorithmic anxiety as a demand that may decrease worker's performance since it is regarded as a source of tension. According to JD-R, transformational leadership is the job resource that helps employees cope with demands and manage their emotional state. Thus, transformational leadership diminishes the algorithmic anxiety's impact on the employees' performance level and negative outcome. Based on JD-R and TCUM theories, there is a basis for proposing the following tentative link that guides this study: transformational leadership (job resource) reduces the algorithmic anxiety's demands (job demand), resulting in a decreased likelihood of undesirable outcome that occurs due to the implementation of artificial intelligence.

3. METHODOLOGY

This study employs a secondary analysis of data and systematic literature review (SLR). The decision to apply this research design was based on three main considerations. First, the nature of

the subject matter itself dictated the choice, as collecting primary data would be exceptionally challenging, if not impossible, given the sensitivity and confidentiality of information on AI adoption. Second, the topic is relatively new; thus, the pool of existing studies to analyze was still limited. Third, the current research is a synthesis of findings on the impact of transformational leadership in different organizational settings, which requires a different approach than a primary study on a single organization could provide.

The analysis is based on the findings of seven articles and various corporate and project-level reports published in 2021-2026. The initial list of sources included items that were evaluated according to three main criteria. First, the manuscripts that were included either explicitly discussed or conceptualized the connection between transformational leadership and the outcomes of algorithmic anxiety or AI adoption. Second, the works had to be published in reputable journals or magazines or originate from respected institutions. Third, the source had to concern either human resource management practices directly or other fields of endeavour where the implications of AI adoption were similarly profound (e.g., healthcare). Those manuscripts that discussed AI adoption exclusively from a technological and design perspective were discarded at this stage. Nevertheless, several such articles were used as background materials.

The current research primarily concentrates on medium- and large-sized organizations as subjects of analysis. This choice was motivated by the fact that such entities are most likely to engage in active and ongoing digital transformation processes on a large scale. Moreover, they tend to possess an established system of management and leadership, have the requisite HR departments, and adopt new technologies, including AI, in their day-to-day operations. Three theoretical frameworks were specifically employed in the analysis of the readings. The first is the theory of communication and uncertainty management (TCUM). The second is the job demands-resources (JD-R) model, and finally, the Transformative Leadership Compass, which several articles used to demonstrate the connections between the four components of transformational leadership and various stages of technology adoption. All these frameworks were used when extracting relevant information from the readings. As for the findings themselves, the emphasis was placed on whether and how transformational leadership affected the level of algorithmic anxiety, AI literacy, self-efficacy, intention to use, and performance outcomes, with all these topics being presented in Section 4.

By its very nature, a secondary study has some inherent limitations, and several of them will be discussed in detail in Section 6. They primarily concern the limitations imposed by the methods used in the original studies, as well as the impossibility of testing new hypotheses directly.

4. ANALYSIS OF TFL AND AI ADAPTABILITY

4.1 Communication as a Catalyst

Across the papers, I see that it is essential to organize effective communication to manage change, specifically introduce a new system. I think transformational leaders do not only talk about information that a new system entails or the features of it but also the ways that it would be different and the specific outcomes that were expected not just from the system but from their employees after the integration of the program. If they managed to discuss it openly, it would reduce the level of conflict since people would see the reasons and expectations but also possible flaws that a system designed to optimize processes would have.

In the context of communication, it is essential to keep the level of support as high as possible because multiple papers mention the fact that the level of psychological well-being of employees who received adequate support from their superiors was positively correlated with their self-efficacy levels when facing stressful and uncertain circumstances. Supervisors play a significant role in keeping an employee's morale high because they are the ones who can answer their questions, assess their concerns as ones not based on their resistance to change but instead address the actual issue. Additionally, I think that communication is vital for introducing a new system because employees can ask clarifying questions, and an open relationship with a supervisor helps an employee feel safe regarding their concerns. The content of communication, as mentioned above, is less important than keeping contact with both sides and being clear about the facts without being overly optimistic about outcomes that a system might not achieve. Multiple sources mention that unproductive communication where the leader tries to make the new system seem better than it is leads to the emergence of scepticism towards it when people realize its shortcomings.

4.2 Enhancing AI Literacy and Self-Efficacy

AI literacy, which refers to the general understanding of interacting with and utilizing AI, is found to be one of the key predictors of the continued use of the technology. Notably, AI literacy is not a one-time learning process, but rather the ability is learned over an extended period, with a supportive environment being vital in the early stages. This is because intellectual stimulation, one of the four aspects of transformational leadership, directly promotes experimentation and critical thinking, as opposed to mere rote learning.

Finally, the study highlights the importance of AI-related efficacy, or employees' beliefs about their ability to produce the desired output with the help of AI. According to Matsunaga's (2021) analysis, transformational leaders are significantly more successful than their peers in mitigating the negative effect of contextual uncertainty on employee efficacy. In another words, two

employees who encounter similar challenges about ambiguity and unpredictability when engaging with AI may well have different levels of efficacy depending on the leadership they are exposed to. This finding has significant implications for ensuring the success of transformation processes by underscoring the importance of leader training.

4.3 TFL and Job Performance

The relationship between TFL and sustained job performance during AI transitions is one of the most consistent findings reported in the literature under review. In a field test conducted among medical professionals, who are at the forefront of adopting AI-assisted diagnostics, algorithmic anxiety was found to undermine self-reported performance levels, with transformational leadership practices by one's supervisor serving as a critical moderator (Kınış, Denizli, & Demirtaş, 2026). Notably, the dampening impact of AI-related anxiety on personal performance was considerably offset when workers were exposed to higher levels of TFL, despite the objective conditions (in terms of the degree of uncertainty) remaining constant.

Transformational leadership helps workers reframe algorithmic uncertainty as a stimulating "challenge" rather than a debilitating "hindrance," thus restoring their cognitive and emotional resources which would otherwise be spent on combating anxiety-provoking circumstances. More specifically, transformational leaders' emphasis on inspirational motivation and individual consideration helps employees achieve a more positive "assessment of the demands and rewards of the work role," effectively countering the demotivating influence of heightened algorithmic anxiety. The underlying mechanism, therefore, rests with transformational leaders' ability to encourage workers to view AI technology not as a "rival" but rather as a "resource." As such, TFL fosters the emergence of a mutually reinforcing relationship between humans and technology, which ultimately manifests in higher levels of discretionary effort and the likelihood of engaging AI assistance in the workplace.

4.4 Comparative Patterns Across Organizational Contexts

While it was found that the relationships between the TFL-anxiety-performance variables were generally strong across the analysed articles, there are disparities in the ways these variables manifested based on the organizational contexts of the studies. For healthcare-related works, algorithm anxiety was linked to the liability of error, which implies that the feared outcome of the use of AI in decision-making processes is an error that has severe consequences. On the contrary, in corporate and administrative works, anxiety was linked to the replacement of a worker with an AI system and the possibility of being replaced. These differences have practical implications, as the most effective behaviours to address anxiety would depend on the primary context where they are applied. Thus, in high-stakes contexts, leaders would benefit most from focusing on idealized influence and providing a complete understanding of responsibility

mechanisms while, in administrative contexts, individualized consideration and inspirational approaches to career development would be more relevant to reducing algorithmic anxiety. In this way, while the overall approach to TFL is generally effective across fields, the specific behaviours should be selected based on the types of anxiety present.

5. DISCUSSION

Taken together, the presented evidence suggests that the success of implementing AI in human resource management (HRM) practice is determined primarily by the effectiveness of the leadership in the context of technology implementation rather than the technology itself. In other words, introducing advanced systems without carefully managing their use at the operational level appears to lead to only mediocre results regardless of technological sophistication. Thus, innovation is a process in which technology application is only one factor that should be considered in combination with others, most notably the human element.

The technology-centric nature of the relationship between AI and its impact on the workplace is not discounted but rather complemented by a consideration of adaptive structuration theory (AST). In brief, AST posits that technology and social action are related historically within an iterative process rather than technology being the driving force that determines outcomes. The practical implication of this nuance is that when viewed from AST's perspective, AI systems in HRM practice do not have inherently prescribed impacts on employees; instead, they are contingent on how workers interact with, navigate, negotiate, and circumvent technology in practice. In this regard, transformational leadership (TFL) represents a critical social force that ensures the effectiveness of organizational change efforts in general and technology implementation in particular. Essentially, TFL embodies the human touch needed to realize the beneficial potential of digital innovation, including AI, in the workplace. It facilitates organizational change processes that optimize the impact of virtual tools and technologies used in HRM. Notably, as found in several of the studies discussed in the paper, TFL supports the development of fluid and trusting interactions between employees and their leaders at work, which in turn promotes the emergence of a positive attitude towards the use of AI in workplace settings. This dynamic illustrates how TFL fosters organizational AI maturity both directly and indirectly.

Finally, as suggested by the findings and discussion section of the paper, while transformational leadership can and does facilitate the successful implementation of technology solutions such as AI in HRM, it often requires tremendous personal effort on the part of the leader to balance their own often-unsure attitudes towards technology with the need to provide each member of their team with individualized guidance and encouragement throughout the process. As such, it is critical for future research to evaluate the question of who, if anyone, helps transformational

leaders in their efforts to balance their own attitudes towards technology and lead by example in the workplace.

6. CHALLENGES AND LIMITATIONS

Several challenges undermine the possibility of applying these findings to practice directly. First is the Black Box Problem, which is especially pertinent to AI systems that use complex machine learning algorithms. Such algorithms are often incomprehensible to the average user, making the software difficult to understand even for technically proficient workers, let alone non-technically inclined employees, whose jobs' outcomes are dictated by the results of this software. This fact significantly limits the extent to which even the most competent leader can provide transparency, as they are only as knowledgeable as the system itself. Economic and Regulatory Friction is another factor that lies beyond the control of the leader or even the HR division in an organization. Some governments have begun considering ways to offset the negative impact of AI-driven automation on the labour market by introducing "automation taxes," which would indirectly influence the strategic choices made by the leadership.

The ethical costs are also difficult to ignore for HR managers. Although they recognize the value of implementing AI to maximize efficiency, reduce errors, and standardize procedures, they are also aware that such decisions come at the expense of people's livelihoods. It is the responsibility of the TFL to make the employees acclimatize to this paradigm, but it cannot eliminate the ethical tension that the company must resolve. Moreover, there is a risk of encountering Digital Inequality, another issue that is beyond the control of HR. Workers who were more technologically inclined at the beginning of the transition to AI systems stand to benefit more from the changes in the long run at the expense of peers who may be less comfortable with technology-driven work. Once again, the TFL is only capable of mitigating the problem but not eliminating it by addressing the employees' skill levels.

Finally, it is important to acknowledge the limitations of this secondary research study. Most of the findings are derived from the review of prior survey studies, which can only provide surface-level insight into employee responses to AI. It is entirely possible that the actual level of support for AI-driven workplace changes is different from what has been presented here due to biases present in the original studies. Additionally, the findings are synthesized from the results of seven studies, which used different measurements and populations, and thus might not be entirely comparable. However, it is safe to say that they reflect moderate levels of agreement across the board, but further investigation is required to conduct a more in-depth analysis of employees' attitudes towards AI in the workplace.

7. RECOMMENDATIONS FOR HRM PROFESSIONALS

Based on the research conducted, the following recommendations for improving people's psychological wellbeing when engaging with AI were developed:

1. Set the limits for human-AI interaction clear: The organization should establish what decisions would be performed by humans, supported by AI, or delegated to AI completely and make this information available to all stakeholders. It would reduce algorithmic anxiety caused by the uncertainty of the role of one's work in the AI-driven workplace.

2. Enhance employees' digital leadership competence: Companies should provide their managers with the resources and knowledge to improve their transformational leadership behaviors in managing digital transformation processes. It refers to educating them on the significance of idealized influence, inspirational motivation, intellectualization, and individualized consideration during human-AI interactions.

3. Build self-sustaining AI communities: Organizations should create communities, where employees could openly share their experiences and concerns regarding AI adoption and participate in testing new AI-driven solutions. It would reduce the risks associated with adopting new technologies due to lack of information or improper training.

4. Ensure ethics in AI strategy: The company's AI strategy should include the core values that would be prioritized during the transition to AI-driven operations. In doing so, the organization would demonstrate its commitment to ethical AI use and gain employees' trust.

5. Create an interactive feedback platform: To ensure employee engagement in the process of digital transformation, the company should introduce interactive platforms where employees could share their suggestions and votes on proposed changes. Such involvement would increase employees' motivation and reduce their anxiety.

6. Provide access to leaders' resources: To improve transformational leadership behaviors, managers need to be provided with leaders' resources and training, as transformational leadership is resource intensive. It means that the company should invest in improving managerial competencies and provide access to peer-to-peer support networks for its managers.

7. Select TFL areas based on organizational needs: Based on the information provided in section 4.4, the areas of transformational leadership, which would be necessary for reducing algorithmic anxiety in different fields, would depend on the primary sources of this type of anxiety. For example, when working with professionals, communication, and accountability, and when working with administration, career development would be more important.

8. CONCLUSION

The paper proves that transformational leadership, and its inspiration motivation and individualized consideration dimensions, can act as a buffer against algorithmic anxiety, preventing the development of negative perceptions of AI in Human Resource Management. The evidence from the 7 studies conducted by the authors and the additional sets of data illustrate that TFL can predetermine the extent to which employees accept new technologies, trust them, and learn to work with them effectively. In other words, transformational leadership, and particularly its two sub-dimensions, can help to restore the confidence and skill levels of the staff members who have been undermined or depleted by the implementation of new technologies.

I find the conclusion of the authors that the use of AI in Human Resource Management is not a "technology-enabled" but a "human-led" process very revealing. The data gathered in the article suggests that for any organization that wants to achieve relatively lasting success in the race towards AI-enabled management, the creation of a human-centred system in which the well-being of people and their ability to communicate with new systems and processes is prioritized is crucial. I agree with the conclusion that in the new environment where many companies are embarking on a journey toward embracing AI, transformational leadership is the key to fostering positive employee perceptions of technology.
